

# Evaluation of 3 mainstream weather forecast models with IJmuiden observations at the North Sea

P.C. Kalverla, G.-J. Steeneveld, R.J. Ronda (KNMI) and **A.A.M. Holtslag** (presenter)

# Use of (mesoscale) weather forecast models

Among others:

Resource assessment

Rodrigues et al., 2015

(Power) forecasting

e.g. Foley et al., 2012

Realistic inflow fields

Sanz Rodrigo et al., 2017

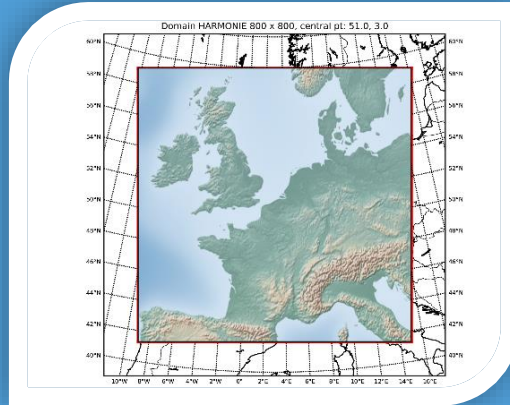

# Research questions

- What is the typical performance of each model for +36h forecasts?
- How much does model performance depend on weather type?
- Does more resolution help to improve results?

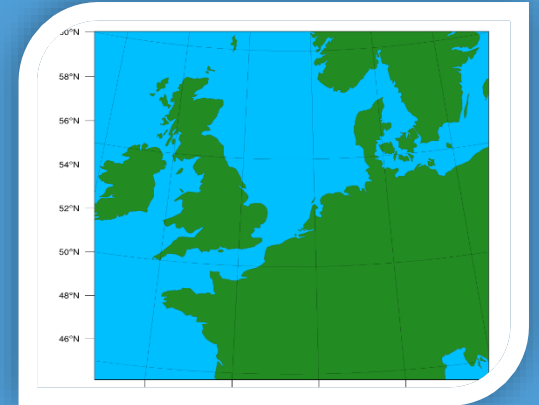

ECMWF-IFS (16km)

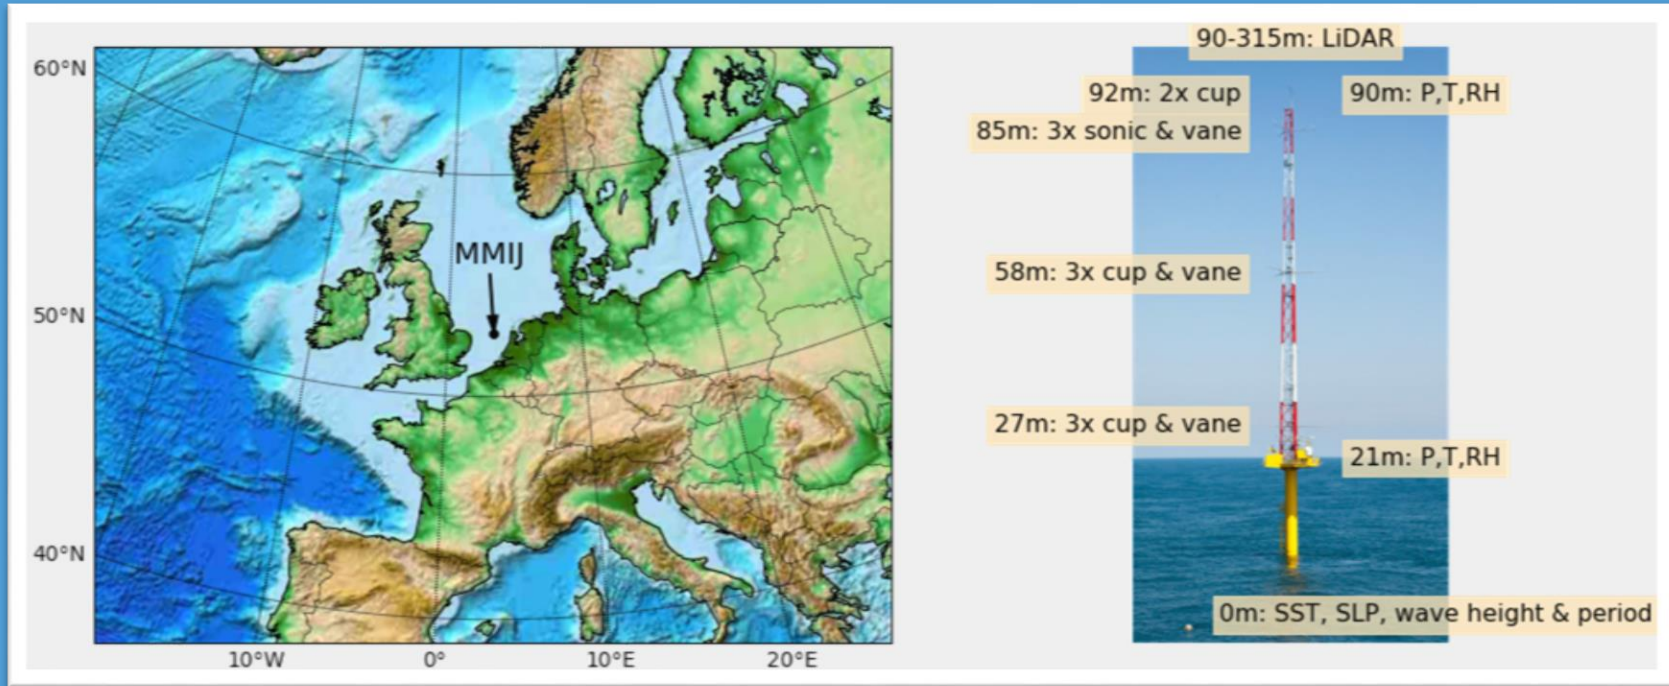

Harmonie (2.5 km)

WRF (3 km)

# Four years of high quality data for validation (2012-2015)

Kalverla et al., 2017, JWEIA – An observational climatology of anomalous wind events ...

# WRF results for wind speed at 115 m

Number of cases in cluster

# Results for +36 h forecasts (case weighted numbers)

All bias:  $< 0.5$  m/s

Typical spread:  $< 2$  m/s

Harmonie:

Smallest bias, largest spread

Impact of more refined data assimilation?

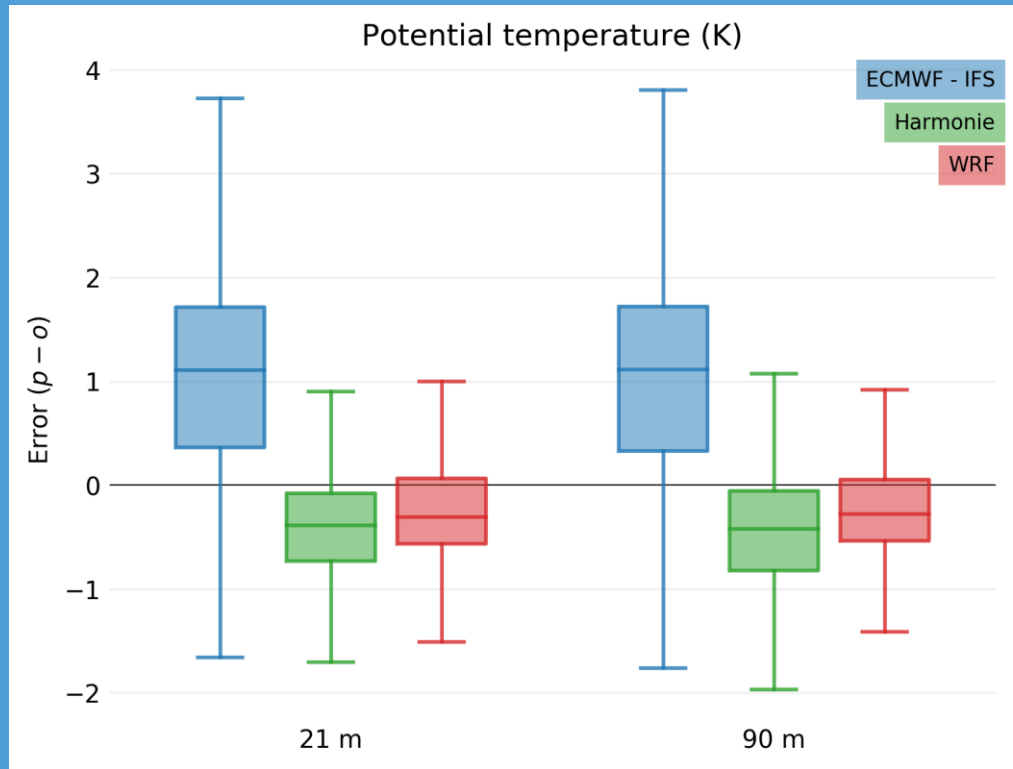

# Results for +36 h forecasts (case weighted numbers)

IFS 1 K too warm

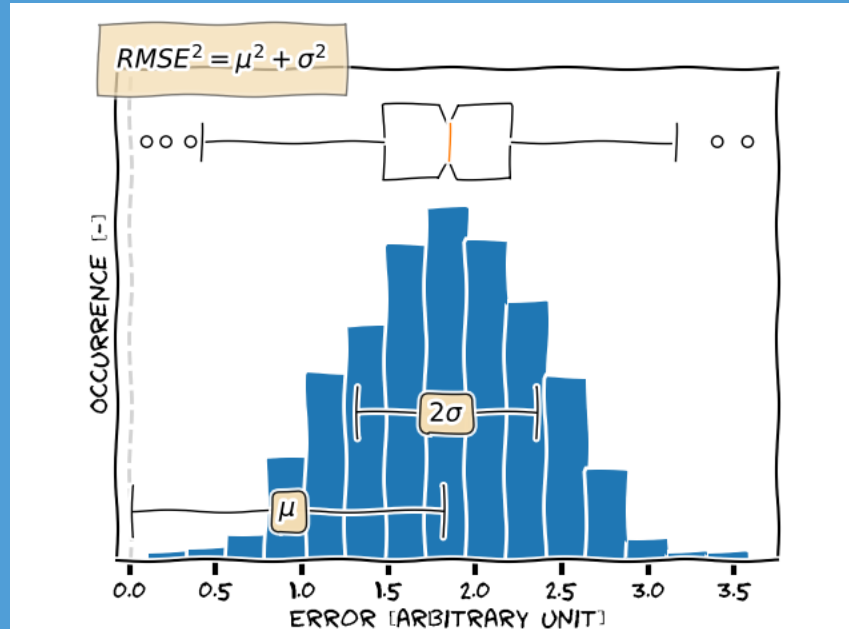

Others too cold

IFS much larger spread

# Introducing error diagrams

For quick comparison of 1<sup>st</sup> and 2<sup>nd</sup> moments of error distributions

## 21m potential temperature

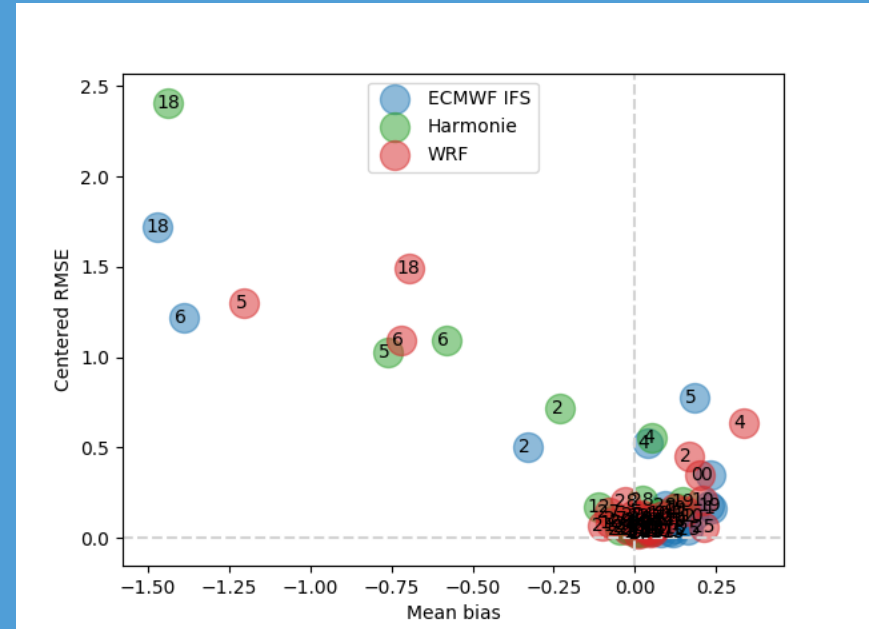

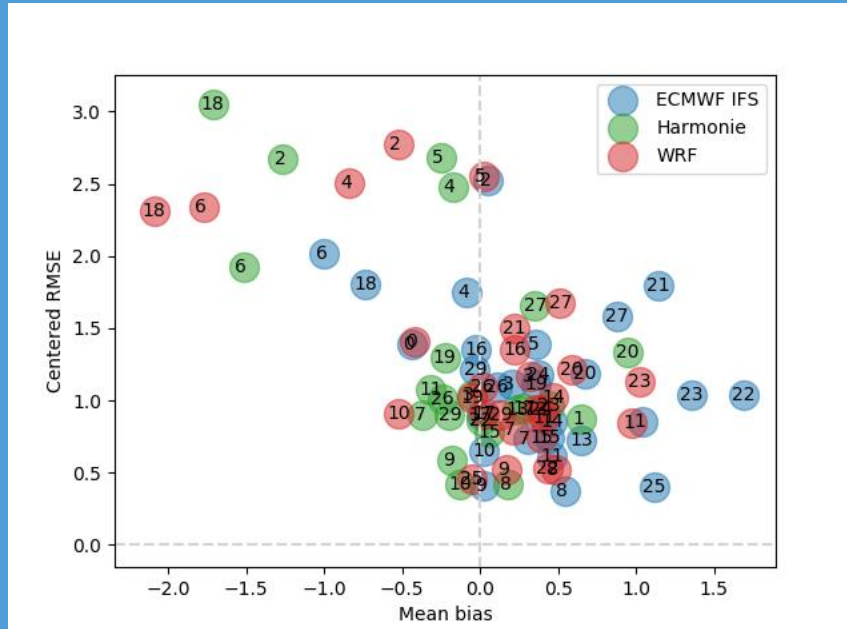

# Models struggle to represent stable conditions (cluster 18)

315m – 27m wind speed difference

90m – 21m virtual potential temp. diff.

# Take home

Wind speed bias  $< 0.5$  m/s

Wind speed error std  $< 2$  m/s

ECMWF temperature bias 1K

Stable conditions most challenging

Not much impact of higher resolution in this study

# Back-up information

# Case selection strategy: "UVS·t<sub>2</sub>" clustering

principle component analysis in 6 dimensions (illustrated here for 2 dimensions)

# Results of clustering algorithm

👍 Cases representative for climatology

👍 Good correlation with local observations

# Additional info: cases

Case 18 most stable

Worst performance

Case 4,5,6 also stable

4,5 weak wind

6: stronger wind

# Additional info: WRF set-up

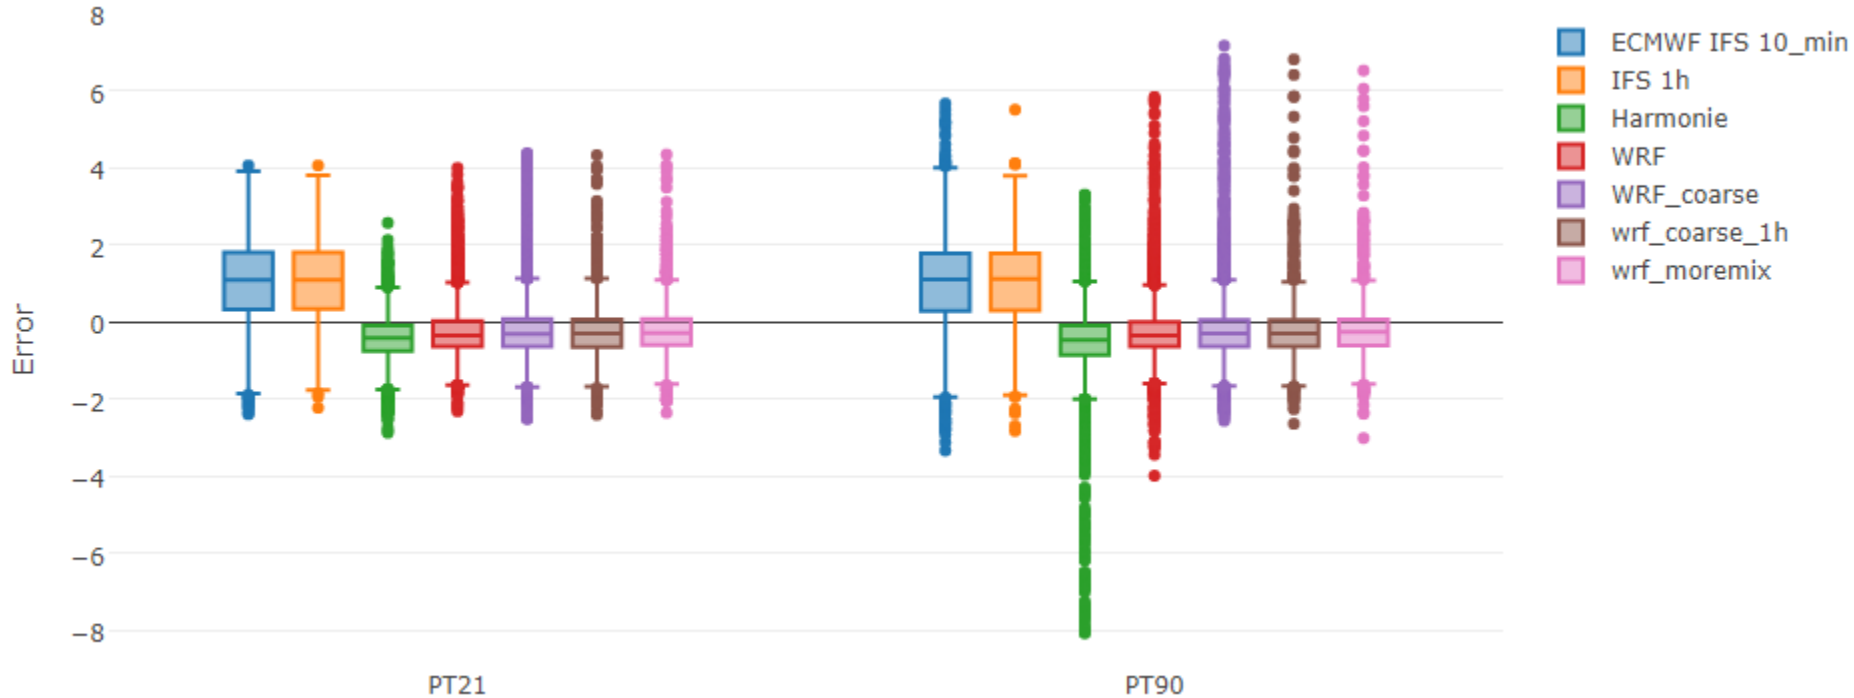

- WRFV3.9
- 600\*600\*91 points; 3 km hor. spacing
- Driven by ECMWF OA (~ 16 km)
- Noah land surface
- New Thompson microphysics
- RRTMG radiation
- Grell-Freitas scale-adaptive cumulus
- MYNN2.5 PBL and SL with mass-flux
  
- Based on 3km HRRR, CONUS/NCAR ensemble and active development

WRF domain (3 km)

# Additional info: additional simulations

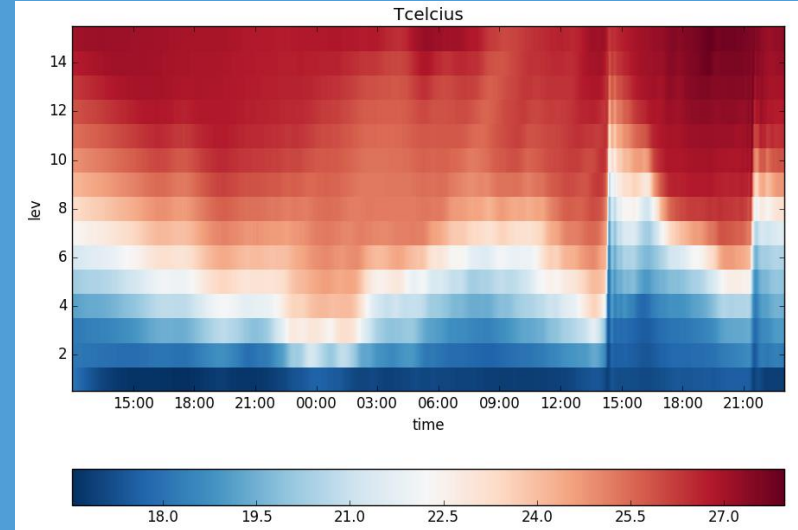

# Additional info

- SST is very well represented in all models
- Harmonie is version V36, new cycle V40 includes new mixing length formulation
- Skill scores were calculated but don't add much to the visual impression
- 10m wind was also evaluated with synops at offshore platforms: similar error patterns

# Additional info: case 5 evolution

~ 560 m

# Case 5: surface charts (saddle point)

2013-07-23 06:00:00

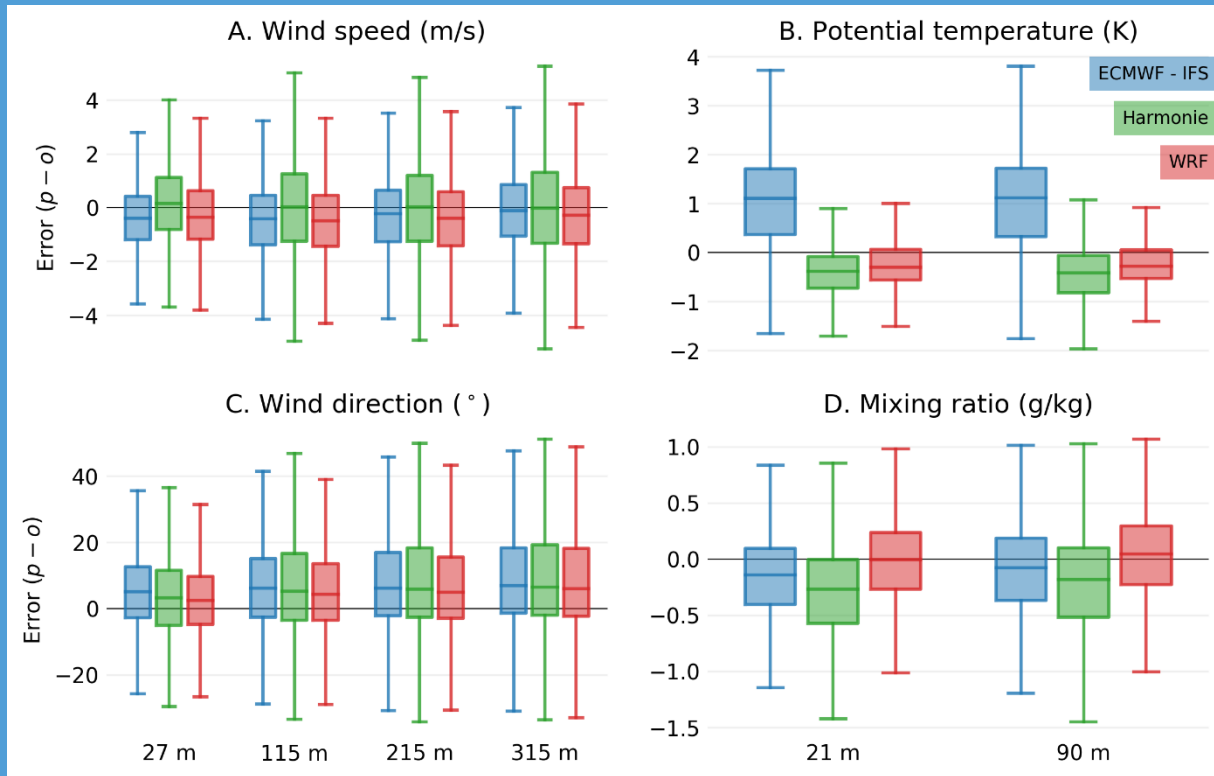

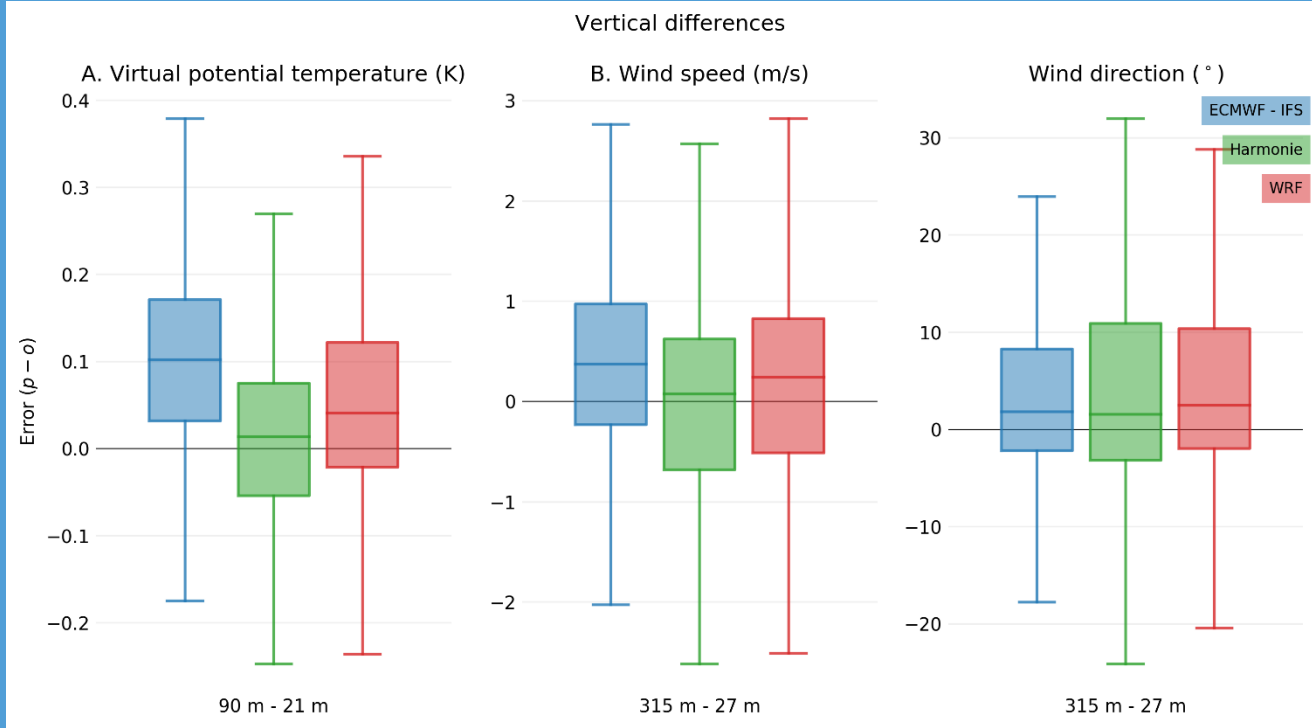

→ 10 m/s

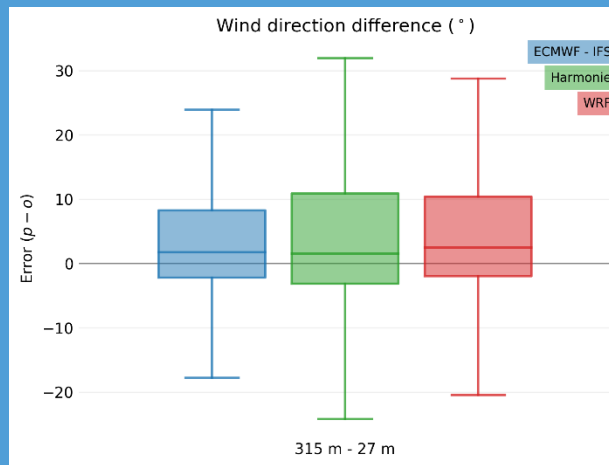

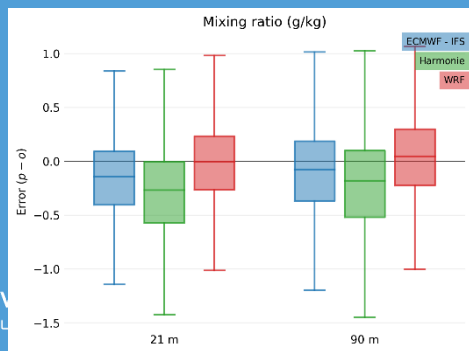

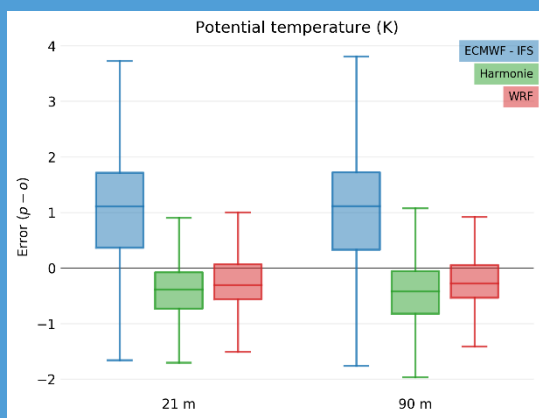

2013-07-23 15:00:00

→ 10 m/s

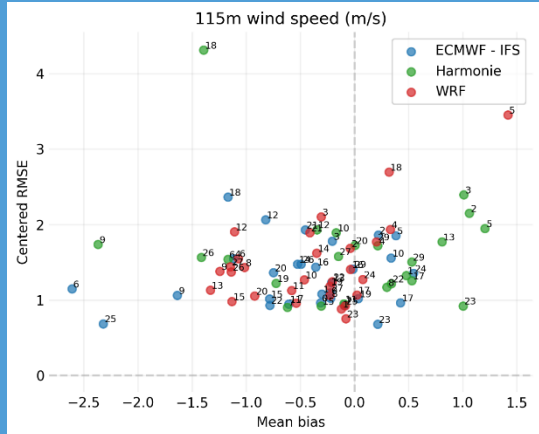

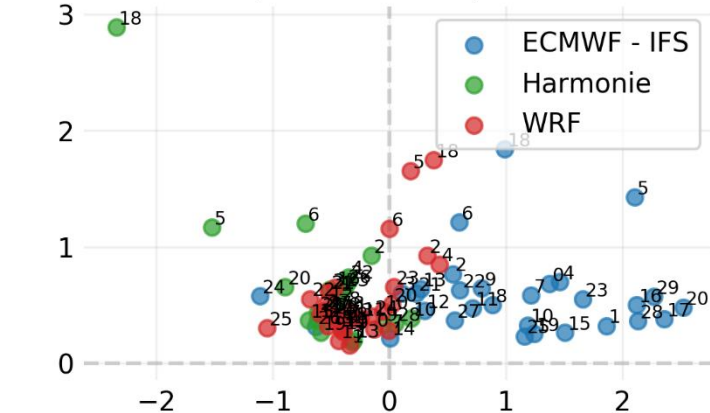

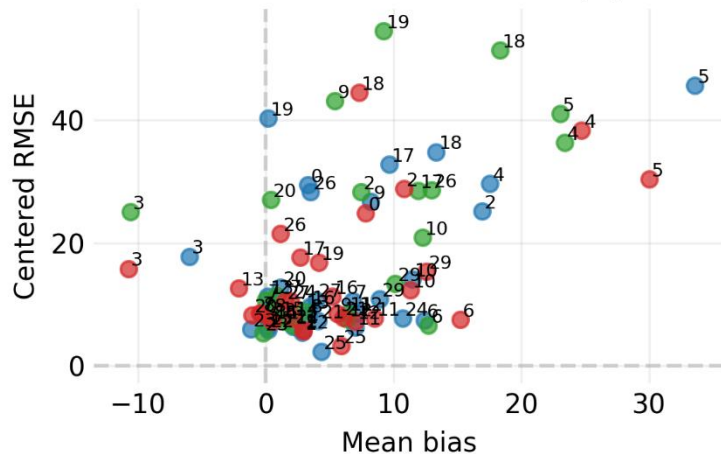

A. 115m wind speed (m/s)

B. 90m potential temperature (K)

C. 115m wind direction (°)

D. 90m mixing ratio (g/kg)
